Cyber Security Vulnerability Assessment Report

Future Interns Cyber Security Internship - Task 1: Web Vulnerability Assessment

Name: Erica Awuah
Repository: FUTURE_CS_01
Date: March 2026
Target Website: testphp.vulnweb.com

Introduction

This report presents a basic vulnerability assessment conducted on the practice website testphp.vulnweb.com. The objective of the assessment was to identify potential security weaknesses through passive reconnaissance techniques using Nmap and browser developer tools. The findings are documented along with their risk level and recommended remediation steps.

Tools Used

1. Nmap - Network scanning and service detection
2. Google Chrome Developer Tools – HTTP header analysis
3. GitHub - documentation and evidence storage

Findings

Finding 1 - Server Version Disclosure
Risk Level: Low

The Nmap scan revealed that port 80 is open and the web server is running nginx version 1.19.0. Exposing server software versions may allow attackers to identify known vulnerabilities associated with that version.

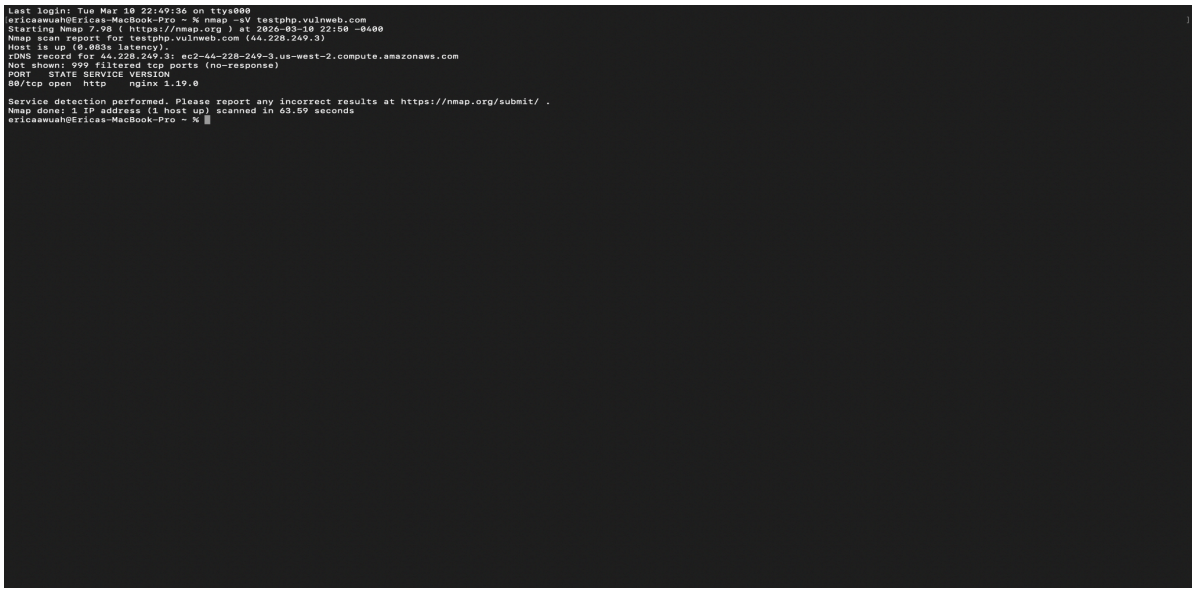
Recommendation: Limit or hide server version information within server configurations.

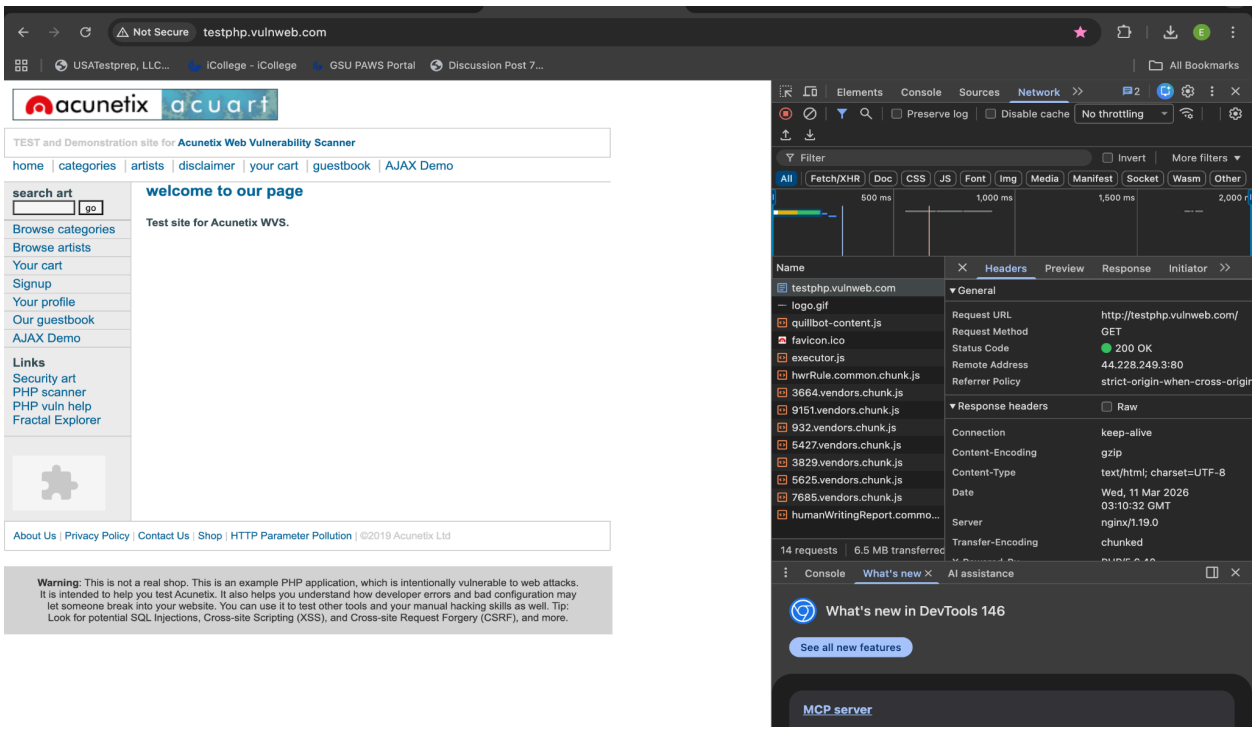
Finding 2 – Information Disclosure in HTTP Headers
Risk Level: Low

The HTTP response headers exposed the web server software and version information. Such disclosures can assist attackers in fingerprinting the system.

Recommendation: Disable unnecessary server header information and configure secure HTTP headers.

Evidence





The following screenshots support the findings identified in this assessment: Nmap scan results showing open port 80 and nginx server version. HTTP header inspection using Chrome Developer Tools.

Conclusion

The assessment identified minor information disclosure issues related to server version exposure and HTTP header configuration. Although the risk level is low, addressing these issues would improve the overall security posture of the web application.
